## Inequalities related to weighted averages

- So far, it is quite natural to hypothesize that the value of
- $_{3}$   $\epsilon,\gamma\text{-trimmed}$  mean should be monotonically related to the
- breakdown point in a semiparametric distribution, since it is
- 5 a linear combination of quantile averages as shown in Section
- 6 ??. Analogous to the  $\gamma$ -orderliness, the  $\gamma$ -trimming inequality
- 7 for a right-skewed distribution is defined as  $\forall 0 \leq \epsilon_1 \leq \epsilon_2 \leq$
- 8  $\frac{1}{1+\gamma}$ ,  $TM_{\epsilon_1,\gamma} \geq TM_{\epsilon_2,\gamma}$ .  $\gamma$ -orderliness is a sufficient condition
- $_{9}$   $\,$  for the  $\gamma\text{-trimming}$  inequality, as proven in the SI Text. The
- next theorem shows a relation between the  $\epsilon, \gamma$ -quantile average
- and the  $\epsilon, \gamma$ -trimmed mean under the  $\gamma$ -trimming inequality,
- suggesting the  $\gamma$ -orderliness is not a necessary condition for
- the  $\gamma$ -trimming inequality.
- 14 Theorem .1. For a distribution that is right-skewed and
- 5 follows the  $\gamma$ -trimming inequality, it is asymptotically true
- that the quantile average is always greater or equal to the
- 17 corresponding trimmed mean with the same  $\epsilon$  and  $\gamma$ .
